# ROBOTICS

Chapter 4 – Trajectory Planning Class Lecture

#### • CONTENTS:

Chapter 1: Introduction

Chapter 2: Kinematics

Chapter 3: Differential Kinematics and Statics

# Chapter 4: Trajectory Planning

Chapter 5: Actuators and Sensors

Chapter 6: Control Architecture

#### 4. TRAJECTORY PLANNING

#### □ Trajectory planning:

Senerate the reference inputs to the motion control system which ensures that the manipulator executes the planned trajectories

Generating a time sequence of the values attained by an interpolating function (typically a polynomial) of the desired trajectory

Some techniques for trajectory generation:

✓ *Point-to-point motion* 

✓ Motion through a sequence of points

دانشکدہ مہندسی مکانیک – درس رہاتیک

# 4.1 PATH AND TRAJECTORY

□ The difference between a path and a trajectory:

- A path denotes the locus of points in the joint space, or in the operational space, which the manipulator has to follow in the execution of the assigned motion (a pure geometric description of motion).
- A trajectory is a path on which a timing law is specified, for instance in terms of velocities and/or accelerations at each point.
- □ The inputs to a trajectory planning algorithm:
  - Path description, Path constraints, Constraints imposed by manipulator dynamics
- □ The outputs of a trajectory planning algorithm:
  - The end-effector trajectories in terms of a time sequence of the values attained by position, velocity and acceleration

دانشکدہ مہندسی مکانیک – درس رہاتیک

# 4.2 JOINT SPACE TRAJECTORIES

- To plan a trajectory in the joint space, the values of the joint variables have to be determined first from the end-effector position and orientation.
- It is then necessary to resort to an inverse kinematics algorithm, if planning is done off-line, or to directly measure the above variables, if planning is done by the teaching-by-showing technique.
- □ The planning algorithm generates a function q(t) interpolating the given vectors of joint variables at each point, in respect of the imposed constraints.

## 4.2 JOINT SPACE TRAJECTORIES

□ Joint space trajectory planning algorithm features:

- The generated trajectories should be not very demanding from a computational viewpoint
- The joint positions and velocities should be continuous functions of time (continuity of accelerations may be imposed, too)
- Undesirable effects should be minimized, e.g. nonsmooth trajectories interpolating a sequence of points on a path.
- At first, only the initial and final points on the path and the traveling time are specified (point-to-point).
- □ Then intermediate points along the path are specified (motion through a sequence of points).
- □ Without loss of generality, the single joint variable q(t) is considered.

دانشکدہ مہندسی مکانیک – درس رہاتیک

- □ In point-to-point motion, the manipulator has to move from an initial to a final joint configuration in a given time  $t_{f}$ .
- □ In this case, the actual end-effector path is of no concern.
- □ The algorithm should generate a trajectory which is also capable of optimizing some performance index.

□ The analysis of an incremental motion problem:

- $\bullet$  *I* : the moment of inertia
- ♦  $q_i$ : initial value
- ♦  $q_f$ : final value

*t<sub>f</sub>*: final time
 *τ*: torque supplied by motor

□ A solution which minimizes the energy dissipated in the motor:

$$I\dot{\omega} = \tau \quad \longrightarrow \quad \int_{o}^{t_{f}} \omega(t)dt = q_{f} - q_{i}$$

\* Performance Index:

$$\int_0^{t_f} \tau^2(t) dt \quad \longrightarrow \quad \omega(t) = at^2 + bt + c$$

□ The *cubic polynomial* 

$$q(t) = a_3 t^3 + a_2 t^2 + a_1 t + a_0$$
  

$$\Rightarrow \dot{q}(t) = 3a_3 t^2 + 2a_2 t + a_1$$
  

$$\Rightarrow \ddot{q}(t) = 6a_3 t + 2a_2$$

Determination of a specific trajectory

$$a_{0} = q_{i}$$

$$a_{1} = \dot{q}_{i}$$

$$a_{3}t_{f}^{3} + a_{2}t_{f}^{2} + a_{1}t_{f} + a_{0} = q_{f}$$

$$3a_{3}t_{f}^{2} + 2a_{2}t_{f} + a_{1} = \dot{q}_{f}$$

□ Time history of position, velocity and acceleration with a cubic polynomial timing law  $q(t) = a_3 t^3 + a_2 t^2 + a_1 t + a_0$ 

If it is desired to assign also the initial and final values of acceleration, six constraints have to be satisfied:

$$q(t) = a_5t^5 + a_4t^4 + a_3t^3 + a_2t^2 + a_1t + a_0$$

دانشکده مهندسی مکانیک – درس رباتیک

- An alternative approach with timing laws of blended polynomial type is frequently adopted in industrial practice, which allows a direct verification of whether the resulting velocities and accelerations can be supported by the physical mechanical manipulator.
- □ In this case, a trapezoidal velocity profile is assigned, which imposes a constant acceleration in the start phase, a cruise velocity, and a constant deceleration in the arrival phase.

□ *Trapezoidal velocity profile:* Characterization of a timing law

□ Time history of position, velocity and acceleration with a trapezoidal velocity profile timing law

- □ In several applications, the path is described in terms of a number of points greater than two.
- □ For instance, even for the simple point-to-point motion of a pick-and-place task, it may be worth assigning two intermediate points between the initial point and the final point.
- □ For more complex applications, it may be convenient to assign a sequence of points so as to guarantee better monitoring on the executed trajectories.
- □ Therefore, the problem is to generate a trajectory when N points, termed path points, are specified and have to be reached by the manipulator at certain instants of time.

□ The interpolating polynomial of lowest order is the cubic polynomial, since it allows the imposition of continuity of velocities at the path points

□ Time history of position, velocity and acceleration with a timing law of interpolating polynomials with velocity constraints at path points

□ Interpolating linear polynomials with parabolic blends

#### **Chapter 4 - Trajectory Planning**

# 4.2.2 Motion Through a Sequence of Points

□ Interpolating linear polynomials with parabolic blends

## 4.3 OPERATIONAL SPACE TRAJECTORIES

- □ A joint space trajectory planning algorithm generates a time sequence of values for the joint variables q(t) so that the manipulator is taken from the initial to the final configuration.
- □ The resulting end-effector motion is not easily predictable, in view of the nonlinear effects introduced by direct kinematics.
- □ Whenever it is desired that the end-effector motion follows a geometrically specified path in the operational space, it is necessary to plan trajectory execution directly in the same space.
